

Data Note

This policy brief is based on open geodata from GeoNorge. Three datasets were used: registered public shelters from DSB, population on a 1 × 1 km grid from SSB, and municipal boundaries from Kartverket.

The analysis measures geographic proximity to registered public shelters. For each populated 1 × 1 km grid cell, the straight-line distance from the grid cell centre to the nearest registered public shelter was calculated. The population in each grid cell was then assigned to one of four distance categories: within 500 meters, 500 meters to 1 kilometer, 1 to 2 kilometers, or more than 2 kilometers. These results were then summarized nationally and at municipal level.

The analysis only includes registered public shelters in the DSB/GeoNorge dataset. Private and semi-public shelters are not included, and Svalbard is excluded. The results should therefore be read as a measure of proximity to registered public shelter infrastructure, not as a full assessment of Norway's total shelter capacity.

There are also important limits to what the analysis can show. It does not assess shelter condition, maintenance, capacity, operational readiness, legal access, or actual walking distance in a crisis. Straight-line distance is useful for comparing geographic patterns, but real-world access may be more difficult.

The analyses behind this policy brief are available on GitHub. This includes the mapping of registered public shelters across Norway and the proximity calculations used in the brief.
